

Extinction Needs to Be Prevented

What is extinction? Because of the increase in the number of factories and human population, nature is getting affected in a negative way. The negative effects on nature results in the extinction which means an end for endangered species. One of the many debates about extinction of endangered species is whether it is a part of the evolution and therefore no need to try to prevent it or people need to prevent it since it has negative effects. Extinction of the endangered species should be prevented since it is harmful to nature and it has a negative impact on global economy.

Firstly, extinction should be prevented since the extinction of even one species may lead to a disaster for nature. In nature, each organism has a role. Cho (2019) states that "A balanced and biodiverse ecosystem is one in which each species plays an important role and relies on the services

provided by other species to survive" (p. 1). In other words, each species' role is vital for a healthy ecosystem. That is why even one of the species can affect the whole ecosystem. Cho (2019) claims that losing one species results in making other species which live around it more fragile, which can lead to a domino effect. The important point here is that the number of extinction may increase easily and extinction may cause hardship for nature. To sum up, extinction of endangered species may lead to the extinction of other species and therefore it is a big threat for nature.

In addition to the impact on nature, extinction affects global economy negatively. Industries that are based on the products of animals get hurt because of the extinction. For example, Cho (2019) states that "Atlantic Cod in the waters off of Newfoundland, which has formed the basis of the local economy since the 15th century — until

Overfishing the cod destroyed the livelihoods of local fishermen" (p. 2). The important point here is that, these animal-based industries vanished with the extinction and they can no more contribute to the global economy. Also, the effects of extinction on economy is too big to overcome. According to Cho (2019), the continuation of extinction can cost 18 percent of economy by 2050. This means a lot of industry will either disappear or get affected negatively. As a result, extinction is not a problem just for nature but also for people.

On the other hand, some people claim that extinction of endangered species is not important. They believe that whether other species live or get extinct is not important since it is a part of evolution. Therefore, they think extinction has no bad or good effect on the world. Pyron (2017) claims that "The world is no better or worse for the absence of saber-toothed tigers and dodo birds

and our Neanderthal cousins, who died off as Homo sapiens evolved" (p. 2). This means, the condition of the world is not dependent on the extinction of species. For this reason, some people do not view the extinction of endangered species as a threat to world. Though it is true that extinction is a part of evolution, opponents overlook the fact that endangered species' extinction makes the world worse. Cho (2019) states that "The consequences of extinction are far-reaching but not always easy to observe. We may not realize how much of the natural world has been lost because the 'baseline' shifts with every generation" (p. 2). It can be said that extinction has effects which cannot be seen from today's perspective. As a result, contrary to some people's opinions, extinction may have negative effects which cannot be observed.

All in all, extinction of endangered

species affects the whole ecosystem negatively. In addition to affecting the nature, extinction results in hurting the economical industries and therefore the global economy. Though some people think extinction does not make the world better or worse, extinction may have adverse effect on the world, which cannot be observed. All the species can get extinct in the future if people do not prevent the extinction of endangered species.
